Two unequal likelihood maxima: does the MLE find the global one?
≤ 1e-6
(converged)
global-max
threshold
1 start, wrong basin: 0.0% at global max
4 posterior draws: 97.0% at global max
wrong + best 3 of 32 screened
(compare() default): 99.8% at global max
rows (of 400, log scale)
log-likelihood shortfall below the global maximum (nats, per row)
